

## PERSONAL LEARNER CHECKLIST KS4

# **GCSE Chemistry (Combined)**

**Parent Curriculum Information:** 

# **Combined Science**

Subject: Combined (Trilogy) Science

Year Group: 11

Subject Leader: Mr Bradley

Email address: g.bradley@becketonline.co.uk

What syllabus is being	AQA Combined Science, Trilogy
taught? What are the key topics and themes? When will they be taught? How will my son or daughter be assessed? When do these assessments take place?	<ul> <li>Learners following a Combined Science pathway will sit two GCSEs in Science which are a combination of Biology, Chemistry and Physics content</li> <li>Both GCSEs offer the potential to sit Higher (grade 9 to 4) or Foundation (grade 5 to 1) papers</li> <li>There are six examinations in the summer of Year 11: two for Biology, two for Chemistry and two for Physics. Each exam will last 1 hour and 15 minutes and is worth 70 marks. The "Required Practicals" taught during lesson time will also be assessed on the exams</li> <li>Biology Paper 1 - Cell Biology; Organisation; Infection and response; and Bioenergetics</li> <li>Biology Paper 2 - Homeostasis and response; Inheritance, variation and evolution; and Ecology</li> <li>Chemistry Paper 1 - Atomic structure and the periodic table; Bonding, structure, and the properties of matter; Quantitative chemistry; Chemical changes; and Energy changes</li> <li>Chemistry Paper 2 - The rate and extent of chemical change; Organic chemistry; Chemical analysis; Chemistry of the atmosphere; and Using resources</li> <li>Physics Paper 1 - Energy; Electricity; Particle model of matter; and Atomic</li> </ul>
What can my son or daughter do for revision at home? What materials are provided or available online?	structure Physics Paper 2 - Forces; Waves; and Magnetism and electromagnetism - Use a CGP Combined Science revision guide that they can purchase from the school - Make use of their classwork booklets - Make use of Seneca, through the following link: www.senecalearning.com - Make use of Quizlet, through the following link: www.quizlet.com - Access BBC Bitesize, through the following link: www.bbc.co.uk/education/subjects/zrkw2hv - Attempt past papers by following this procedure: www.aqa.org.uk/exams-administration/exams-guidance/find-past-papers-and- mark-schemes - Access Physics and Maths tutor, through the following link: https://www.physicsandmathstutor.com/ This contains revision materials for ALL sciences not just physics

## <u>C1 - Atomic structure and the periodic table</u>

Ра	Part 1:					
At	oms, elements and compounds					
	All substances are made of atoms. An atom is the smallest part of an element that can exist.					
	Atoms of each element are represented by a chemical symbol, eg O represents an atom of oxygen, Na represents an atom of sodium.					
	There are about 100 different elements. Elements are shown in the periodic table.					
	Students will be supplied with a periodic table for the exam and should be able to:					
	<ul> <li>use the names and symbols of the first 20 elements in the periodic table, the elements in Groups 1 and 7, and other elements in this specification</li> </ul>					

Mi	xtures		
	A mixture consists of two or more elements or compounds not chemically combined together. The chemical properties of each substance in the mixture are unchanged.		
	Mixtures can be separated by physical processes such as filtration, crystallisation, simple distillation, fractional distillation and chromatography. These physical processes do not involve chemical reactions and no new substances are made.		
	Students should be able to:		
	describe, explain and give examples of the specified processes of separation		
	<ul> <li>suggest suitable separation and purification techniques for mixtures when given appropriate information.</li> </ul>		

Th	e development of the model of the atom		
	New experimental evidence may lead to a scientific model being changed or replaced.		
	Before the discovery of the electron, atoms were thought to be tiny spheres that could not be divided.		
	The discovery of the electron led to the plum pudding model of the atom. The plum pudding model suggested that the atom is a ball of positive charge with negative electrons embedded in it.		
	The results from the alpha particle scattering experiment led to the conclusion that the mass of an atom was concentrated at the centre (nucleus) and that the nucleus was charged. This nuclear model replaced the plum pudding model.		
	Niels Bohr adapted the nuclear model by suggesting that electrons orbit the nucleus at specific distances. The theoretical calculations of Bohr agreed with experimental observations.		
	Later experiments led to the idea that the positive charge of any nucleus could be subdivided into a whole number of smaller particles, each particle having the same amount of positive charge. The name proton was given to these particles.		
	The experimental work of James Chadwick provided the evidence to show the existence of neutrons within the nucleus. This was about 20 years after the nucleus became an accepted scientific idea.		
	Students should be able to describe:		
	<ul> <li>why the new evidence from the scattering experiment led to a change in the atomic model</li> </ul>		
	<ul> <li>the difference between the plum pudding model of the atom and the nuclear model of the atom.</li> </ul>		

Re	lative electrical charges of subatomic particles					
	The relative electrical charges of the particles in atoms are:		Name of particle	Relative charge		
		-	Proton	+1	-	
		-	Neutron	0		
			Electron	-1		
	In an atom, the number of electrons is equal to the number of Atoms have no overall electrical charge.	protons i	n the nuc	leus.		
	The number of protons in an atom of an element is its atomic r particular element have the same number of protons. Atoms o different numbers of protons.					
	Students should be able to use the nuclear model to describe a	ntoms.				
Siz	e and mass of atoms					
	Atoms are very small, having a radius of about 0.1 nm (1 x $10^{-10}$	<sup>o</sup> m).				
	The radius of a nucleus is less than 1/10 000 of that of the atom	n (about :	1 x 10 <sup>-14</sup> n	n).		
	Almost all of the mass of an atom is in the nucleus.					
	The relative masses of protons, neutrons and electrons are:	Name partic		elative lass		
		Proton	1	1		
		Neutro	n	1		
		Electro	on Ve	ry small		
	The sum of the protons and neutrons in an atom is its mass nu	mber.				
	Atoms of the same element can have different numbers of neu called isotopes of that element.	itrons; th	ese atoms	s are		
	Atoms can be represented as shown in this example:					
	(Mass number) 23 (Atomic number) 11 Students should be able to calculate the numbers of protons, r atom or ion, given its atomic number and mass number.		and electr	ons in an		
Re	lative atomic mass					

ne			
	The relative atomic mass of an element is an average value that takes account of the		
	abundance of the isotopes of the element.	l I	
	Students should be able to calculate the relative atomic mass of an element given the		
	percentage abundance of its isotopes.		

Electronic structure		
<ul> <li>The electrons in an atom occupy the lowest available energy levels (innermost available shells). The electronic structure of an atom can be represented by numbers or by a diagram. For example, the electronic structure of sodium is 2,8,1 or:</li> </ul>		
showing two electrons in the lowest energy level, eight in the second energy level and one in		
the third energy level.		
Students may answer questions in terms of either energy levels or shells.		
<ul> <li>Students should be able to represent the electronic structures of the first twenty elements of the periodic table in both forms.</li> </ul>		

#### Part 2:

Th	e periodic table		
	The elements in the periodic table are arranged in order of atomic (proton) number and so that elements with similar properties are in columns, known as groups. The table is called a periodic table because similar properties occur at regular intervals.		
	Elements in the same group in the periodic table have the same number of electrons in their outer shell (outer electrons) and this gives them similar chemical properties.		
	Students should be able to:		
	<ul> <li>explain how the position of an element in the periodic table is related to the arrangement of electrons in its atoms and hence to its atomic number</li> </ul>		
	<ul> <li>predict possible reactions and probable reactivity of elements from their positions in the periodic table.</li> </ul>		

De	velopment of the periodic table		
	Before the discovery of protons, neutrons and electrons, scientists attempted to classify the elements by arranging them in order of their atomic weights.		
	The early periodic tables were incomplete and some elements were placed in in inappropriate groups if the strict order of atomic weights was followed.		
	Mendeleev overcame some of the problems by leaving gaps for elements that he thought had not been discovered and in some places changed the order based on atomic weights.		
	Elements with properties predicted by Mendeleev were discovered and filled the gaps. Knowledge of isotopes made it possible to explain why the order based on atomic weights was not always correct.		
	Students should be able to describe these steps in the development of the periodic table.		

M	etals and non-metals		
	Elements that react to form positive ions are metals.		
	Elements that do not form positive ions are non-metals.		
	The majority of elements are metals. Metals are found to the left and towards the bottom of the periodic table. Non-metals are found towards the right and top of the periodic table.		
	Students should be able to:		
•	explain the differences between metals and non-metals on the basis of their characteristic physical and chemical properties.		
•	explain how the atomic structure of metals and non-metals relates to their position in the periodic table		
	<ul> <li>explain how the reactions of elements are related to the arrangement of electrons in their atoms and hence to their atomic number.</li> </ul>		

Gr	oup 0		
	The elements in Group 0 of the periodic table are called the noble gases. They are unreactive and do not easily form molecules because their atoms have stable arrangements of electrons. The noble gases have eight electrons in their outer shell, except for helium, which has only two electrons.		
	The boiling points of the noble gases increase with increasing relative atomic mass (going down the group).		
	Students should be able to:		
	<ul> <li>explain how properties of the elements in Group 0 depend on the outer shell of electrons of the atoms</li> </ul>		
	<ul> <li>predict properties from given trends down the group.</li> </ul>		

Gr	oup 1		
	The elements in Group 1 of the periodic table are known as the alkali metals and have characteristic properties because of the single electron in their outer shell.		
	Students should be able to describe the reactions of the first three alkali metals with oxygen, chlorine and water.		
	In Group 1, the reactivity of the elements increases going down the group.		
	Students should be able to:		
	<ul> <li>explain how properties of the elements in Group 1 depend on the outer shell of electrons of the atoms</li> </ul>		
	<ul> <li>predict properties from given trends down the group.</li> </ul>		

Gr	oup 7		
	The elements in Group 7 of the periodic table are known as the halogens and have similar reactions because they all have seven electrons in their outer shell. The halogens are non-metals and consist of molecules made of pairs of atoms.		
	Students should be able to describe the nature of the compounds formed when chlorine, bromine and iodine react with metals and non-metals.		
	In Group 7, the further down the group an element is the higher its relative molecular mass, melting point and boiling point.		
	In Group 7, the reactivity of the elements decreases going down the group.		
	A more reactive halogen can displace a less reactive halogen from an aqueous solution of its salt.		
	Students should be able to:		
	<ul> <li>explain how properties of the elements in Group 7 depend on the outer shell of electrons of the atoms</li> </ul>		
	<ul> <li>predict properties from given trends down the group.</li> </ul>		

## C2 - Bonding, structure, and the properties of matter

#### Part 1: Chemical bonds, ionic, covalent and metallic

Chemical bonds	R	Α	G
There are three types of strong chemical bonds: ionic, covalent and metallic. For ionic bonding			
the particles are oppositely charged ions.			
For covalent bonding the particles are atoms which share pairs of electrons. For metallic			
bonding the particles are atoms which share delocalised electrons.			
Ionic bonding occurs in compounds formed from metals combined with non-metals.			
Covalent bonding occurs in most non-metallic elements and in compounds of non-metals.			
Metallic bonding occurs in metallic elements and alloys.			
Students should be able to explain chemical bonding in terms of electrostatic forces and the			
transfer or sharing of electrons.			

Ionic bonding	R	Α	G
When a metal atom reacts with a non-metal atom electrons in the outer shell of the metal			
atom are transferred. Metal atoms lose electrons to become positively charged ions. Non-			
metal atoms gain electrons to become negatively charged ions. The ions produced by metals in			
Groups 1 and 2 and by non-metals in Groups 6 and 7 have the electronic structure of a noble			
gas (Group 0).			
The electron transfer during the formation of an ionic compound can be represented by a dot			
and cross diagram, eg for sodium chloride.			
$Na \bullet + \stackrel{\times}{} \overset{\times}{\overset{\times}{\overset{\times}{\overset{\times}{\overset{\times}{\overset{\times}{\overset{\times}$			
(2,8,1) (2,8,7) (2,8) (2,8,8)			
Students should be able to draw dot and cross diagrams for ionic compounds formed by metals			
in Groups 1 and 2 with non-metals in Groups 6 and 7.			
The charge on the ions produced by metals in Groups 1 and 2 and by non-metals in Groups 6			
and 7 relates to the group number of the element in the periodic table.			
Students should be able to work out the charge on the ions of metals and non-metals from the			
group number of the element, limited to the metals in Groups 1 and 2, and non-metals in			
Groups 6 and 7.			

Ionic compounds	R	Α	G
An ionic compound is a giant structure of ions. Ionic compounds are held together by strong			
electrostatic forces of attraction between oppositely charged ions. These forces act in all			
directions in the lattice and this is called ionic bonding.			
The structure of sodium chloride can be represented in the following forms:			
$\mathbf{Key} \\ \mathbf{Na^{+}} \\ \mathbf{C} \\ $			

8

Studer	nts should be able to:		
•	deduce that a compound is ionic from a diagram of its structure in one of the specified forms		
•	describe the limitations of using dot and cross, ball and stick, two and three- dimensional diagrams to represent a giant ionic structure		
•	work out the empirical formula of an ionic compound from a given model or diagram that shows the ions in the structure.		
•	Students should be familiar with the structure of sodium chloride but do not need to know the structures of other ionic compounds.		

Covalent bonding	R	Α	G
When atoms share pairs of electrons, they form covalent bonds.			
These bonds between atoms are strong.			
Covalently bonded substances may consist of small molecules.			
Students should be able to recognise common substances that consist of small molecules from			
their chemical formula.			
Some covalently bonded substances have very large molecules, such as polymers.			
Some covalently bonded substances have giant covalent structures, such as diamond and			
silicon dioxide.			
The covalent bonds in molecules and giant structures can be represented in the following			
forms:			
For ammonia (NH <sub>3</sub> ) and/or			
×× ××			
Hồ N <sub>ố</sub> h			
$\left(\begin{array}{c} H \end{array}\right) N \left(\begin{array}{c} H \end{array}\right) + \begin{array}{c} N \\ H \end{array}\right)$			
Н			
and/or and/or			
H-N-H			
H H			
Polymers can be represented in the form:			
$\begin{pmatrix} H & H \\ H & H \end{pmatrix}$			
$+\dot{c}-\dot{c}+$			
$\begin{pmatrix} H & H \end{pmatrix}$ n			
poly(ethene) where n is a large number.			
Students should be able to:			
draw dot and cross diagrams for the molecules of hydrogen, chlorine, oxygen, nitrogen,			
hydrogen chloride, water, ammonia and methane			
<ul> <li>represent the covalent bonds in small molecules, in the repeating units of polymers</li> </ul>			
and in part of giant covalent structures, using a line to represent a single bond			
<ul> <li>describe the limitations of using dot and cross, ball and stick, two and three-</li> </ul>			
dimensional diagrams to represent molecules or giant structures			

 deduce the molecular formula of a substance from a given model or diagram in these forms showing the atoms and bonds in the molecule.

Metallic bonding	R	Α	G
Metals consist of giant structures of atoms arranged in a regular pattern.			
The electrons in the outer shell of metal atoms are delocalised and so are free to move through			
the whole structure. The sharing of delocalised electrons gives rise to strong metallic bonds.			
The bonding in metals may be represented in the following form:			
Delocalised electrons			

#### Part 2: How bonding and structure are related to the properties of substances

The three states of matter	R	Α	G
The three states of matter are solid, liquid and gas. Melting and freezing take place at the			
melting point, boiling and condensing take place at the boiling point.			
The three states of matter can be represented by a simple model. In this model, particles are			
represented by small solid spheres. Particle theory can help to explain melting, boiling, freezing			
and condensing.			
The amount of energy needed to change state from solid to liquid and from liquid to gas			
depends on the strength of the forces between the particles of the substance. The nature of			
the particles involved depends on the type of bonding and the structure of the substance.			
The stronger the forces between the particles the higher the melting point and boiling point of			
the substance.			
(HT only) Limitations of the simple model above include that in the model there are no forces,			
that all particles are represented as spheres and that the spheres are solid.			
Students should be able to:			
<ul> <li>predict the states of substances at different temperatures given appropriate data</li> </ul>			
<ul> <li>explain the different temperatures at which changes of state occur in terms of</li> </ul>			
<ul> <li>energy transfers and types of bonding</li> <li>recognise that atoms themselves do not have the bulk properties of materials</li> </ul>			
(HT only) explain the limitations of the particle theory in relation to changes of state when			
particles are represented by solid inelastic spheres which have no forces between them.			

State symbols	R	Α	G
In chemical equations, the three states of matter are shown as (s), (l) and (g), with (aq) for			
aqueous solutions.			
Students should be able to include appropriate state symbols in chemical equations for the			
reactions in this specification.			

Properties of ionic compounds	R	Α	G
Ionic compounds have regular structures (giant ionic lattices) in which there are strong			
electrostatic forces of attraction in all directions between oppositely charged ions.			
These compounds have high melting points and high boiling points because of the large			
amounts of energy needed to break the many strong bonds.			
When melted or dissolved in water, ionic compounds conduct electricity because the ions are			
free to move and so charge can flow.			
Knowledge of the structures of specific ionic compounds other than sodium chloride is not			
required.			

Properties of small molecules	R	Α	G
Substances that consist of small molecules are usually gases or liquids that have relatively low			
melting points and boiling points.			
These substances have only weak forces between the molecules (intermolecular forces). It is			
these intermolecular forces that are overcome, not the covalent bonds, when the substance			
melts or boils.			
The intermolecular forces increase with the size of the molecules, so larger molecules have			
higher melting and boiling points.			
These substances do not conduct electricity because the molecules do not have an overall			
electric charge.			
Students should be able to use the idea that intermolecular forces are weak compared with			
covalent bonds to explain the bulk properties of molecular substances.			

Polymers	R	Α	G
Polymers have very large molecules. The atoms in the polymer molecules are linked to other			
atoms by strong covalent bonds. The intermolecular forces between polymer molecules are			
relatively strong and so these substances are solids at room temperature.			
Students should be able to recognise polymers from diagrams showing their bonding and			
structure.			

Giant covalent structures	R	Α	G
Substances that consist of giant covalent structures are solids with very high melting points. All			
of the atoms in these structures are linked to other atoms by strong covalent bonds. These			
bonds must be overcome to melt or boil these substances. Diamond and graphite (forms of			
carbon) and silicon dioxide (silica) are examples of giant covalent structures.			
Students should be able to recognise giant covalent structures from diagrams showing their			
bonding and structure.			

Properties of metals and alloys	R	Α	G
Metals have giant structures of atoms with strong metallic bonding.			
This means that most metals have high melting and boiling points.			
In pure metals, atoms are arranged in layers which allows metals to be bent and shaped. Pure			

metals are too soft for many uses and so are mixed with other metals to make alloys which are		
harder.		
Students should be able to explain why alloys are harder than pure metals in terms of		
distortion of the layers of atoms in the structure of a pure metal.		

Metals as conductors	R	Α	G
Metals are good conductors of electricity because the delocalised electrons in the metal carry			
electrical charge through the metal. Metals are good conductors of thermal energy because			
energy is transferred by the delocalised electrons.			

#### Part 3: Structure and bonding of carbon

Diamond	R	Α	G
In diamond, each carbon atom forms four covalent bonds with other carbon atoms in a giant			
covalent structure, so diamond is very hard, has a very high melting point and does not			
conduct electricity.			
Students should be able to explain the properties of diamond in terms of its structure and			
bonding.			

Graphite	R	Α	G
In graphite, each carbon atom forms three covalent bonds with three other carbon atoms,			
forming layers of hexagonal rings which have no covalent bonds between the layers.			
In graphite, one electron from each carbon atom is delocalised.			
Students should be able to explain the properties of graphite in terms of its structure and			
bonding.			
Students should know that graphite is similar to metals in that it has delocalised electrons.			

Graphene and fullerenes	R	Α	G
Graphene is a single layer of graphite and has properties that make it useful in electronics and			
composites.			
Students should be able to explain the properties of graphene in terms of its structure and			
bonding.			
Fullerenes are molecules of carbon atoms with hollow shapes. The structure of fullerenes is			
based on hexagonal rings of carbon atoms but they may also contain rings with five or seven			
carbon atoms. The first fullerene to be discovered was Buckminsterfullerene (C60) which has a			
spherical shape.			
Carbon nanotubes are cylindrical fullerenes with very high length to diameter ratios. Their			
properties make them useful for nanotechnology, electronics and materials.			
Students should be able to:			
<ul> <li>recognise graphene and fullerenes from diagrams and descriptions of their</li> </ul>			
bonding and structure			
<ul> <li>give examples of the uses of fullerenes, including carbon nanotubes.</li> </ul>			

### **C3** - Quantitative Chemistry

#### Part 1: Chemical measurements, conservation of mass and the quantitative interpretation of chemical equations

Conservation of mass and balanced chemical equations	R	Α	G
The law of conservation of mass states that no atoms are lost or made during a chemical			
reaction so the mass of the products equals the mass of the reactants.			
This means that chemical reactions can be represented by symbol equations, which are			
balanced in terms of the numbers of atoms of each element involved on both sides of the			
equation.			
Students should understand the use of the multipliers in equations in normal script before a			
formula and in subscript within a formula.			
Relative formula mass	R	Α	G
The relative formula mass (Mr) of a compound is the sum of the relative atomic masses of the			
atoms in the numbers shown in the formula. In a balanced chemical equation, the sum of the			
relative formula masses of the reactants in the quantities shown equals the sum of the relative			
formula masses of the products in the quantities shown.			
Mass changes when a reactant or product is a gas	R	Α	G
Some reactions may appear to involve a change in mass but this can usually be explained			
because a reactant or product is a gas and its mass has not been taken into account. For			
example: when a metal reacts with oxygen the mass of the oxide produced is greater than the			
mass of the metal or in thermal decompositions of metal carbonates carbon dioxide is			
produced and escapes into the atmosphere leaving the metal oxide as the only solid product.			
Students should be able to explain any observed changes in mass in non-enclosed systems			
during a chemical reaction given the balanced symbol equation for the reaction and explain			
these changes in terms of the particle model.			
Chemical measurements	R	Α	G
Whenever a measurement is made there is always some uncertainty about the result obtained.			
Students should be able to:			
<ul> <li>represent the distribution of results and make estimations of uncertainty</li> </ul>			
• use the range of a set of measurements about the mean as a measure of uncertainty.			

#### Part 2: Use of amount of substance in relation to masses of pure substances

Moles (HT only)	R	Α	G
Chemical amounts are measured in moles. The symbol for the unit mole is mol.			
The mass of one mole of a substance in grams is numerically equal to its relative formula mass.			
One mole of a substance contains the same number of the stated particles, atoms, molecules or			
ions as one mole of any other substance.			
The number of atoms, molecules or ions in a mole of a given substance is the Avogadro			
constant. The value of the Avogadro constant is 6.02 x 1023 per mole.			
Students should understand that the measurement of amounts in moles can apply to atoms,			
molecules, ions, electrons, formulae and equations, for example that in one mole of carbon (C)			
the number of atoms is the same as the number of molecules in one mole of carbon dioxide			
(CO2).			
Students should be able to use the relative formula mass of a substance to calculate the number			
of moles in a given mass of that substance and vice versa.			
Amounts of substances in equations (HT only)	R	Α	G
The masses of reactants and products can be calculated from balanced symbol equations.			
Chemical equations can be interpreted in terms of moles. For example:			
$Mg + 2HCI \rightarrow MgCl_2 + H_2$			
shows that one mole of magnesium reacts with two moles of hydrochloric acid to produce one			
mole of magnesium chloride and one mole of hydrogen gas.			

Students should be able to:			
calculate the masses of substances shown in a balanced symbol equation			
• calculate the masses of reactants and products from the balanced symbol equation and the			
mass of a given reactant or product.			
Using moles to balance equations (HT only)	R	Α	G
The balancing numbers in a symbol equation can be calculated from the masses of reactants and			
products by converting the masses in grams to amounts in moles and converting the numbers of			
moles to simple whole number ratios.			
Students should be able to balance an equation given the masses of reactants and products.			
Students should be able to change the subject of a mathematical equation.			
Limiting reactants (HT only)	R	Α	G
In a chemical reaction involving two reactants, it is common to use an excess of one of the			
reactants to ensure that all of the other reactant is used. The reactant that is completely used			
up is called the limiting reactant because it limits the amount of products.			
Students should be able to explain the effect of a limiting quantity of a reactant on the amount			
of products it is possible to obtain in terms of amounts in moles or masses in grams.			
Concentration of solutions	R	Α	G
Many chemical reactions take place in solutions. The concentration of a solution can be			
measured in mass per given volume of solution, e.g. grams per dm3 (g/dm3).			
Students should be able to:			
• calculate the mass of solute in a given volume of solution of known concentration in terms of			
mass per given volume of solution			
• (HT only) explain how the mass of a solute and the volume of a solution is related to the			
concentration of the solution.			

## C4 - Chemical Changes

Part 1 - Description		
Reactions of acids with metals		
Acids react with some metals to produce salts and hydrogen.		
(HT ONLY) Students should be able to:		
<ul> <li>explain in terms of gain or loss of electrons, that these are redox reactions</li> </ul>		
• identify which species are oxidised and which are reduced in given chemical equations.		
Knowledge of reactions limited to those of magnesium, zinc and iron with hydrochloric and		
sulfuric acids.		
Neutralisation of acids and salt production		
Acids are neutralised by alkalis (eg soluble metal hydroxides) and bases (eg insoluble metal		
hydroxides and metal oxides) to produce salts and water, and by metal carbonates to produce		
salts, water and carbon dioxide		
The particular salt produced in any reaction between an acid and base or alkali depends on:		
• the acid used (hydrochloric acid produces chlorides, nitric acid produces nitrates, sulfuric acid		
produces sulfates)		
<ul> <li>the positive ions in the base, alkali or carbonate.</li> </ul>		
Students should be able to:		
<ul> <li>predict products from given reactants</li> </ul>		
<ul> <li>use the formulae of common ions to deduce the formulae of salts.</li> </ul>		
Soluble salts		
Soluble salts can be made from acids by reacting them with solid insoluble substances, such as		
metals, metal oxides, hydroxides or carbonates. The solid is added to the acid until no more		
reacts and the excess solid is filtered off to produce a solution of the salt		
Salt solutions can be crystallised to produce solid salts.		
Students should be able to describe how to make pure, dry samples of named soluble salts from		
information provided.		
<b>Required practical 1:</b> preparation of a pure, dry sample of a soluble salt from an insoluble oxide		
or carbonate using a Bunsen burner to heat dilute acid and a water bath or electric heater to		
evaporate the solution.		

#### Part 2 - Description

The pH scale and neutralisation		
Acids produce hydrogen ions (H <sup>+</sup> ) in aqueous solutions.		
Aqueous solutions of alkalis contain hydroxide ions (OH <sup>-</sup> ).		
The pH scale, from 0 to 14, is a measure of the acidity or alkalinity of a solution, and can be measured using universal indicator or a pH probe.		
A solution with pH 7 is neutral. Aqueous solutions of acids have pH values of less than 7 and aqueous solutions of alkalis have pH values greater than 7.		
In neutralisation reactions between an acid and an alkali, hydrogen ions react with hydroxide ions to produce water.		

This reaction can be represented by the equation:		
$H^+(aq) + OH^-(aq) \rightarrow H_2O(I)$		
Hydrogen ion → Hydroxide ion → Water		
Students should be able to:		
<ul> <li>describe the use of universal indicator or a wide range indicator to measure the approximate pH of a solution</li> </ul>		
<ul> <li>use the pH scale to identify acidic or alkaline solutions.</li> </ul>		
Titrations (chemistry only)		
The volumes of acid and alkali solutions that react with each other can be measured by titration using a suitable indicator.		
describe how to carry out titrations using strong acids and strong alkalis only (sulfuric, hydrochloric and nitric acids only) to find the reacting volumes accurately		
(HT Only) calculate the chemical quantities in titrations involving concentrations in mol/dm3 and in g/dm3 .		
Required practical 2: (chemistry only) determination of the reacting volumes of solutions of a strong acid and a strong alkali by titration		
Strong and weak acids (HIGHER TIER ONLY)		
A strong acid is completely ionised in aqueous solution. Examples of strong acids are hydrochloric, nitric and sulfuric acids.		
A weak acid is only partially ionised in aqueous solution. Examples of weak acids are ethanoic, citric and carbonic acids.		
For a given concentration of aqueous solutions, the stronger an acid, the lower the pH.		
As the pH decreases by one unit, the hydrogen ion concentration of the solution increases by a factor of 10.		
Students should be able to: • use and explain the terms dilute and concentrated (in terms of amount of substance), and weak and strong (in terms of the degree of ionisation) in relation to acids describe neutrality and relative acidity in terms of the effect on hydrogen ion concentration and the numerical value of pH (whole numbers only).		

Part 3 - Description		
Reactivity of metals		
Metal oxides		
Metals react with oxygen to produce metal oxides. The reactions are oxidation reactions because		
the metals gain oxygen.		
Students should be able to explain reduction and oxidation in terms of loss or gain of oxygen.		
The reactivity series		
When metals react with other substances the metal atoms form positive ions. The reactivity of a		
metal is related to its tendency to form positive ions. Metals can be arranged in order of their		
reactivity in a reactivity series. The metals potassium, sodium, lithium, calcium, magnesium, zinc,		
iron and copper can be put in order of their reactivity from their reactions with water and dilute		
acids.		
The non-metals hydrogen and carbon are often included in the reactivity series.		
A more reactive metal can displace a less reactive metal from a compound.		
Students should be able to recall and describe the reactions, if any, of potassium, sodium,		
lithium, calcium, magnesium, zinc, iron and copper with water or dilute acids and where		
appropriate, to place these metals in order of reactivity		
Students should be able to explain how the reactivity of metals with water or dilute acids is		
related to the tendency of the metal to form its positive ion	<u> </u>	
Students should be able to deduce an order of reactivity of metals based on experimental		
results.	<u> </u>	
The reactions of metals with water and acids are limited to room temperature and do not		
include reactions with steam.		
Extraction of metals and reduction		
Unreactive metals such as gold are found in the Earth as the metal itself but most metals are		
found as compounds that require chemical reactions to extract the metal.	<u> </u>	
Metals less reactive than carbon can be extracted from their oxides by reduction with carbon.		
Reduction involves the loss of oxygen.		
Knowledge and understanding are limited to the reduction of oxides using carbon.	<u> </u>	
Knowledge of the details of processes used in the extraction of metals is not required.	<u> </u>	
Students should be able to interpret or evaluate specific metal extraction processes when given		
appropriate information.	<u> </u>	
Students should be able to identify the substances which are oxidised or reduced in terms of		
gain or loss of oxygen.		
Oxidation and reduction in terms of electrons (HT only)		
Oxidation is the loss of electrons and reduction is the gain of electrons.	<b>⊢</b>	
Student should be able to write ionic equations for displacement reactions.	<b>└───</b>	
Students should be able to identify in a given reaction, symbol equation or half equation which		
species are oxidised and which are reduced.		

Part 4 - Description		
Electrolysis		
The process of electrolysis		
When an ionic compound is melted or dissolved in water, the ions are free to move about within		
the liquid or solution. These liquids and solutions are able to conduct electricity and are called		
electrolytes.		
Passing an electric current through electrolytes causes the ions to move to the electrodes.		
Positively charged ions move to the negative electrode (the cathode), and negatively charged		
ions move to the positive electrode (the anode). Ions are discharged at the electrodes producing		
elements. This process is called electrolysis.		
(HT only) Throughout Higher Tier students should be able to write half equations for the		
reactions occurring at the electrodes during electrolysis, and may be required to complete and		
balance supplied half equations.		
Electrolysis of molten ionic compounds		
When a simple ionic compound (e.g. lead bromide) is electrolysed in the molten state using inert		
electrodes, the metal (lead) is produced at the cathode and the non-metal (bromine) is produced		
at the anode.		
Students should be able to predict the products of the electrolysis of binary ionic compounds in		
the molten state.		
Using electrolysis to extract metals		
Metals can be extracted from molten compounds using electrolysis. Electrolysis is used if the		
metal is too reactive to be extracted by reduction with carbon or if the metal reacts with carbon.		
Large amounts of energy are used in the extraction process to melt the compounds and to		
produce the electrical current.		
Aluminium is manufactured by the electrolysis of a molten mixture of aluminium oxide and		
cryolite using carbon as the positive electrode (anode).		
Students should be able to explain why a mixture is used as the electrolyte		
Students should be able to explain why the positive electrode must be continually replaced.		
Electrolysis of aqueous solutions		
The ions discharged when an aqueous solution is electrolysed using inert electrodes depend on		
the relative reactivity of the elements involved.		
At the negative electrode (cathode), hydrogen is produced if the metal is more reactive than		
hydrogen.		
At the positive electrode (anode), oxygen is produced unless the solution contains halide ions		
when the halogen is produced.		
This happens because in the aqueous solution water molecules break down producing hydrogen		
ions and hydroxide ions that are discharged.		
Students should be able to predict the products of the electrolysis of aqueous solutions		
containing a single ionic compound.		
Required practical 3: investigate what happens when aqueous solutions are electrolysed using		
inert electrodes. This should be an investigation involving developing a hypothesis.		
Representation of reactions at electrodes as half equations (HT only)		
During electrolysis, at the cathode (negative electrode), positively charged ions gain electrons		
and so the reactions are reductions.		
At the anode (positive electrode), negatively charged ions lose electrons and so the reactions are		
oxidations.		
Reactions at electrodes can be represented by half equations, for example:		
$2H^+ + 2e^- \rightarrow H_2$		
$40H^{-} \rightarrow O_2 + 2H_2O + 4e^{-}$		
$40H^{2} - 4e^{2} \rightarrow O_{2} + 2H_{2}O$		
	Ĺ	I

## C5 - Energy Changes

Part 1: Exothermic and endothermic reactions		
Energy transfer during exothermic and endothermic reactions		
Energy is conserved in chemical reactions. The amount of energy in the universe at the end of a		
chemical reaction is the same as before the reaction takes place. If a reaction transfers energy to		
the surroundings the product molecules must have less energy than the reactants, by the amount		
transferred.		
An exothermic reaction is one that transfers energy to the surroundings so the temperature of the		
surroundings increases.		
Exothermic reactions include combustion, many oxidation reactions and neutralisation.		
Everyday uses of exothermic reactions include self-heating cans and hand warmers.		
An endothermic reaction is one that takes in energy from the surroundings so the temperature of		
the surroundings decreases. Endothermic reactions include thermal decompositions and the reaction of citric acid and sodium		
hydrogencarbonate. Some sports injury packs are based on endothermic reactions.		
Students should be able to:		
<ul> <li>distinguish between exothermic and endothermic reactions on the basis of the</li> </ul>		
temperature change of the surroundings		
<ul> <li>evaluate uses and applications of exothermic and endothermic reactions given</li> </ul>		
appropriate information.		
Limited to measurement of temperature change. Calculation of energy changes or $\Delta H$ is not		
required.		
Required practical 4: investigate the variables that affect temperature changes in reacting		
solutions such as, eg acid plus metals, acid plus carbonates, neutralisations, displacement of		
metals.		
Reaction profiles		
Chemical reactions can occur only when reacting particles collide with each other and with		
sufficient energy. The minimum amount of energy that particles must have to react is called the		
activation energy.		
Reaction pro les can be used to show the relative energies of reactants and products, the		
activation energy and the overall energy change of a reaction.		
Students should be able to:		
<ul> <li>draw simple reaction pro les (energy level diagrams) for exothermic and endothermic</li> </ul>		
reactions showing the relative energies of reactants and products, the activation energy and		
the overall energy change, with a curved line to show the energy as the reaction proceeds		
<ul> <li>use reaction pro les to identify reactions as exothermic or endothermic</li> </ul>		
<ul> <li>explain that the activation energy is the energy needed for a reaction to occur.</li> </ul>		
(HT only) The energy change of reactions		
During a chemical reaction:		
energy must be supplied to break bonds in the reactants		
<ul> <li>energy is released when bonds in the products are formed.</li> </ul>		
The energy needed to break bonds and the energy released when bonds are formed can be		
calculated from bond energies.		
The difference between the sum of the energy needed to break bonds in the reactants and the		
sum of the energy released when bonds in the products are formed is the overall energy change		
of the reaction.		
In an exothermic reaction, the energy released from forming new bonds is greater than the		

energy needed to break existing bonds.		
In an endothermic reaction, the energy needed to break existing bonds is greater than the energy		
released from forming new bonds.		
Students should be able to calculate the energy transferred in chemical reactions using bond		
energies supplied.		

## C6 - Rate and Extent of a Reaction

Part 1: Rate of reaction		
Calculating rates of reactions		
The rate of a chemical reaction can be found by measuring the quantity of a reactant used or the quantity of product formed over time:		
mean rate of reaction = quantity of reactant used time taken OR		
mean rate of reaction = quantity of product formed time taken		
The quantity of reactant or product can be measured by the mass in grams or by a volume in $\mbox{cm}^3$ .		
The units of rate of reaction may be given as g/s or cm <sup>3</sup> /s.		
<b>(HT only)</b> students are also required to use quantity of reactants in terms of moles and units for rate of reaction in mol/s.		
Students should be able to calculate the mean rate of a reaction from given information about the quantity of a reactant used or the quantity of a product formed and the time taken		
Students should be able to draw, and interpret, graphs showing the quantity of product formed or quantity of reactant used up against time		
Students should be able to draw tangents to the curves on these graphs and use the slope of the tangent as a measure of the rate of reaction		
<b>(HT only)</b> Students should be able to calculate the gradient of a tangent to the curve on these graphs as a measure of rate of reaction at a specific time.		
Factors which affect the rates of chemical reactions		
Factors which affect the rates of chemical reactions include: the concentrations of reactants in solution, the pressure of reacting gases, the surface area of solid reactants, the temperature and the presence of catalysts.		
Students should be able to recall how changing these factors affects the rate of chemical reactions.		
<b>Required practical 5:</b> investigate how changes in concentration affect the rates of reactions by a method involving measuring the volume of a gas produced and a method involving a change in colour or turbidity.		
	<u> </u>	I

Collision theory and activation energy		
Collision theory explains how various factors affect rates of reactions. According to this theory,		
chemical reactions can occur only when reacting particles collide with each other and with		
sufficient energy. The minimum amount of energy that particles must have to react is called the		
activation energy.		
Increasing the concentration of reactants in solution, the pressure of reacting gases, and the		
surface area of solid reactants increases the frequency of collisions and so increases the rate of		
reaction.		
Increasing the temperature increases the frequency of collisions and makes the collisions more		
energetic, and so increases the rate of reaction.		
Students should be able to predict and explain using collision theory the effects of changing		
conditions of concentration, pressure and temperature on the rate of a reaction		
Students should be able to predict and explain the effects of changes in the size of pieces of a		
reacting solid in terms of surface area to volume ratio		
Students should be able to use simple ideas about proportionality when using collision theory to		
explain the effect of a factor on the rate of a reaction.		
Catalysts		
Catalysts change the rate of chemical reactions but are not used up during the reaction.		
Different reactions need different catalysts. Enzymes act as catalysts in biological systems.		
Catalysts increase the rate of reaction by providing a different pathway for the reaction that has		
a lower activation energy.		
A reaction profile for a catalysed reaction can be drawn in the following form:		
Energy Activation Energy without catalyst		
Activation Energy		
with catalyst		
Products		
Progress of reaction		
Students should be able to identify catalysts in reactions from their effect on the rate of reaction		
and because they are not included in the chemical equation for the reaction.		
Students should be able to explain catalytic action in terms of activation energy.		
Students do not need to know the names of catalysts other than those specified in the subject		
content		

Part 2: Reversible reactions and dynamic equilibrium		
Reversible reactions		
In some chemical reactions, the products of the reaction can react to produce the original reactants. Such reactions are called reversible reactions and are represented: $A + B \rightleftharpoons C + D$		
The direction of reversible reactions can be changed by changing the conditions. For example:		
ammonium chloride		
Energy changes and reversible reactions		
If a reversible reaction is exothermic in one direction, it is endothermic in the opposite direction. The same amount of energy is transferred in each case. For example: hydrated copper sulfate (blue) endothermic exothermic exothermic (white)		
Equilibrium		
When a reversible reaction occurs in apparatus which prevents the escape of reactants and products, equilibrium is reached when the forward and reverse reactions occur at exactly the same rate.		
(HT ONLY) The effect of changing conditions on equilibrium		
The relative amounts of all the reactants and products at equilibrium depend on the conditions of the reaction.		
If a system is at equilibrium and a change is made to any of the conditions, then the system responds to counteract the change.		
The effects of changing conditions on a system at equilibrium can be predicted using Le Chatelier's Principle.		
Students should be able to make qualitative predictions about the effect of changes on systems at equilibrium when given appropriate information		
(HT ONLY) The effect of changing concentration		
If the concentration of one of the reactants or products is changed, the system is no longer at equilibrium and the concentrations of all the substances will change until equilibrium is reached again.		
If the concentration of a reactant is increased, more products will be formed until equilibrium is reached again.		
If the concentration of a product is decreased, more reactants will react until equilibrium is reached again.		
Students should be able to interpret appropriate given data to predict the effect of a change in		

concentration of a reactant or product on given reactions at equilibrium.		
(HT ONLY) The effect of temperature changes on equilibrium		
If the temperature of a system at equilibrium is increased:		
• the relative amount of products at equilibrium increases for an endothermic reaction		
• the relative amount of products at equilibrium decreases for an exothermic reaction.		
If the temperature of a system at equilibrium is decreased:		
<ul> <li>the relative amount of products at equilibrium decreases for an endothermic reaction</li> </ul>		
• the relative amount of products at equilibrium increases for an exothermic reaction.		
Students should be able to interpret appropriate given data to predict the effect of a change in		
temperature on given reactions at equilibrium.		
(HT ONLY) The effect of pressure changes on equilibrium		
For gaseous reactions at equilibrium:		
• an increase in pressure causes the equilibrium position to shift towards the side with the		
smaller number of molecules as shown by the symbol equation for that reaction		
• a decrease in pressure causes the equilibrium position to shift towards the side with the larger		
number of molecules as shown by the symbol equation for that reaction.		
Students should be able to interpret appropriate given data to predict the effect of pressure		
changes on given reactions at equilibrium.		

## C7 - Organic Chemistry

#### Part 1: Carbon compounds as fuels and feedstock

Crude oil, hydrocarbons and alkanes			
Crude oil is a finite resource found in rocks. Crude oil is the remains of an ancient biomass			
consisting mainly of plankton that was buried in mud.			
Crude oil is a mixture of a very large number of compounds. Most of the compounds in crude oil			
are hydrocarbons, which are molecules made up of hydrogen and carbon atoms only.			
Most of the hydrocarbons in crude oil are hydrocarbons called alkanes. The general formula for			
the homologous series of alkanes is $C_n H_{2n+2}$			
The first four members of the alkanes are methane, ethane, propane and butane.			
Alkane molecules can be represented in the following forms: C <sub>2</sub> H <sub>6</sub> or H H			
Students should be able to recognise substances as alkanes given their formulae in these forms.			
Students do not need to know the names of specific alkanes other than methane, ethane,			
propane and butane.			
Fractional distillation and petrochemicals			
The many hydrocarbons in crude oil may be separated into fractions, each of which contains			
molecules with a similar number of carbon atoms, by fractional distillation.			
The fractions can be processed to produce fuels and feedstock for the petrochemical industry.			
Many of the fuels on which we depend for our modern lifestyle, such as petrol, diesel oil,			
kerosene, heavy fuel oil and liquefied petroleum gases, are produced from crude oil.			
Many useful materials on which modern life depends are produced by the petrochemical			
industry, such as solvents, lubricants, polymers, detergents.			
The vast array of natural and synthetic carbon compounds occur due to the ability of carbon atoms to form families of similar compounds.			
· · · · · · · · · · · · · · · · · · ·	<u> </u>		
Students should be able to explain how fractional distillation works in terms of evaporation and condensation.			
Knowledge of the names of other specific fractions or fuels is not required.			
Properties of hydrocarbons			
Some properties of hydrocarbons depend on the size of their molecules, including boiling point,			
viscosity and flammability. These properties influence how hydrocarbons are used as fuels.			
Students should be able to recall how boiling point, viscosity and flammability change with			
increasing molecular size.			
The combustion of hydrocarbon fuels releases energy. During combustion, the carbon and			
hydrogen in the fuels are oxidised. The complete combustion of a hydrocarbon produces carbon			

dioxide and water.	
Students should be able to write balanced equations for the complete combustion of	
hydrocarbons with a given formula.	
Knowledge of trends in properties of hydrocarbons is limited to:	
<ul> <li>boiling points</li> <li>viscosity</li> <li>flammability.</li> </ul>	
Cracking and alkenes	
Hydrocarbons can be broken down (cracked) to produce smaller, more useful molecules.	
Cracking can be done by various methods including catalytic cracking and steam cracking.	
Students should be able to describe in general terms the conditions used for catalytic cracking and steam cracking.	
The products of cracking include alkanes and another type of hydrocarbon called alkenes.	
Alkenes are more reactive than alkanes and react with bromine water, which is used as a test for alkenes.	
Students should be able to recall the colour change when bromine water reacts with an alkene.	
There is a high demand for fuels with small molecules and so some of the products of cracking are useful as fuels.	
Alkenes are used to produce polymers and as starting materials for the production of many other chemicals.	
Students should be able to balance chemical equations as examples of cracking given the	
formulae of the reactants and products.	
Students should be able to give examples to illustrate the usefulness of cracking. They should	
also be able to explain how modern life depends on the uses of hydrocarbons	
(For Combined Science: Trilogy and Synergy students do not need to know the formulae or names of individual alkenes.)	

#### **C8** - Chemical Analysis

#### Part 1 Purity, formulations and chromatography

Pure substances		
In chemistry, a pure substance is a single element or compound, not mixed with any other substance.		
Pure elements and compounds melt and boil at specific temperatures. Melting point and boiling point data can be used to distinguish pure substances from mixtures.		
In everyday language, a pure substance can mean a substance that has had nothing added to it, so it is unadulterated and in its natural state, eg pure milk.		
Students should be able to use melting point and boiling point data to distinguish pure from impure substances.		

# FormulationsImage: Complex mixture is a mixture that has been designed as a useful product. Many products are<br/>complex mixtures in which each chemical has a particular purpose. Formulations are made by<br/>mixing the components in carefully measured quantities to ensure that the product has the<br/>required properties. Formulations include fuels, cleaning agents, paints, medicines, alloys,<br/>fertilisers and foods.Image: Components in carefully measured quantities to ensure that the product has the<br/>mixing the components in carefully measured quantities to ensure that the product has the<br/>required properties. Formulations include fuels, cleaning agents, paints, medicines, alloys,<br/>fertilisers and foods.Image: Component is propriate information.Students should be able to identify formulations given appropriate information.Image: Component is proprietary products.Image: Component is proprietary products.

Chromatography		
Chromatography can be used to separate mixtures and can give information to help identify		
substances. Chromatography involves a stationary phase and a mobile phase. Separation		
depends on the distribution of substances between the phases.		
The ratio of the distance moved by a compound (centre of spot from origin) to the distance		
moved by the solvent can be expressed as its Rf value:		
Rf = distance moved by substance distance moved by solvent		
Different compounds have different Rf values in different solvents, which can be used to help		
identify the compounds. The compounds in a mixture may separate into different spots		
depending on the solvent but a pure compound will produce a single spot in all solvents.		
Students should be able to:		
<ul> <li>explain how paper chromatography separates mixtures</li> </ul>		
• suggest how chromatographic methods can be used for distinguishing pure substances from		
impure substances		
<ul> <li>interpret chromatograms and determine Rf values from chromatograms</li> </ul>		
Required practical 6: investigate how paper chromatography can be used to separate and tell the		

difference between coloured substances. Students should calculate Rf values. AT skills covered		
by this practical activity: 1 and 4.		

#### Identification of common gases

#### Test for hydrogen

The test for hydrogen uses a burning splint held at the open end of a test tube of the gas. Hydrogen burns rapidly with a pop sound.

Test for oxygen		
The test for oxygen uses a glowing splint inserted into a test tube of the gas. The splint relights in		
oxygen.		

Test for carbon dioxide		
The test for carbon dioxide uses an aqueous solution of calcium hydroxide (lime water). When		
carbon dioxide is shaken with or bubbled through limewater the limewater turns milky (cloudy).		

Test for chlorine		
The test for chlorine uses litmus paper. When damp litmus paper is put into chlorine gas the		
litmus paper is bleached and turns white.		

## C9 - Chemistry of the Atmosphere

#### Part 1: The composition and evolution of the Earth's atmosphere

The proportions of different gases in the atmosphere		
For 200 million years, the proportions of different gases in the atmosphere have been much		
the same as they are today:		
about four-fifths (approximately 80 %) nitrogen		
<ul> <li>about one-fifth (approximately 20 %) oxygen</li> </ul>		
<ul> <li>small proportions of various other gases, including carbon dioxide</li> </ul>		
water vapour and noble gases.		
The Earth's early atmosphere		
Theories about what was in the Earth's early atmosphere and how the atmosphere was formed		
have changed and developed over time.		
Evidence for the early atmosphere is limited because of the time scale of 4.6 billion years.		
One theory suggests that during the first billion years of the Earth's existence there was intense		
volcanic activity that released gases that formed the early atmosphere and water vapour that		
condensed to form the oceans.		
At the start of this period the Earth's atmosphere may have been like the atmospheres of Mars		
and Venus today, consisting of mainly carbon dioxide with little or no oxygen gas.		
Volcanoes also produced nitrogen which gradually built up in the atmosphere and there may		
have been small proportions of methane and ammonia.		
When the oceans formed carbon dioxide dissolved in the water and carbonates were		
precipitated producing sediments, reducing the amount of carbon dioxide in the atmosphere.		
No knowledge of other theories is required.		
How oxygen increased		
Algae and plants produced the oxygen that is now in the atmosphere by photosynthesis, which		
can be represented by the equation:		
$6CO_2 + 6H_2O \longrightarrow C_6H_{12}O_6 + 6O_2$		
carbon dioxide + water Iight glucose + oxygen		
Algae first produced oxygen about 2.7 billion years ago and soon after this oxygen appeared in		
the atmosphere. Over the next billion years plants evolved and the percentage of oxygen		
gradually increased to a level that enabled animals to evolve.		
How carbon dioxide decreased		
Algae and plants decreased the percentage of carbon dioxide in the atmosphere by		
photosynthesis.		
Carbon dioxide was also decreased by the formation of sedimentary rocks and fossil fuels that		
contain carbon.	<b> </b>	
Students should be able to describe the main changes in the atmosphere over time and some		
of the likely causes of these changes	<u> </u>	
Describe and explain the formation of deposits of limestone, coal, crude oil and natural gas.		

#### Part 2: Carbon dioxide and methane as greenhouse gases

Greenhouse gases		
Greenhouse gases in the atmosphere maintain temperatures on Earth high enough to support		
life. Water vapour, carbon dioxide and methane are greenhouse gases.		
Students should be able to describe the greenhouse effect in terms of the interaction of short		
and long wavelength radiation with matter.		
Human activities which contribute to an increase in greenhouse gases in the atmosphere		
Some human activities increase the amounts of greenhouse gases in the atmosphere. These		
include carbon dioxide and methane.		
Students should be able to recall two human activities that increase the amounts of each of the		
greenhouse gases carbon dioxide and methane.		
Based on peer-reviewed evidence, many scientists believe that human activities will cause the		
temperature of the Earth's atmosphere to increase at the surface and that this will result in		
global climate change.		
However, it is difficult to model such complex systems as global climate change. This leads to		
simplified models, speculation and opinions presented in the media that may be based on only		
parts of the evidence and which may be biased.		
Students should be able to:		
<ul> <li>evaluate the quality of evidence in a report about global climate change given appropriate information</li> </ul>		
<ul> <li>describe uncertainties in the evidence base</li> </ul>		
<ul> <li>recognise the importance of peer review of results and of communicating results to a wide range of audiences.</li> </ul>		

#### Part 3: Climate change and the carbon footprint

Global climate change		
An increase in average global temperature is a major cause of climate change.		
There are several potential effects of global climate change.		
The carbon footprint and its reduction		
The carbon footprint is the total amount of carbon dioxide and other greenhouse gases emitted		
over the full life cycle of a product, service or event.		
The carbon footprint can be reduced by reducing emissions of carbon dioxide and methane.		
Students should be able to:		
describe actions to reduce emissions of carbon dioxide and methane		
<ul> <li>give reasons why actions may be limited.</li> </ul>		

#### Part 4: Common atmospheric pollutants and their sources

Atmospheric pollutants from fuels		
The combustion of fuels is a major source of atmospheric pollutants.		
Most fuels, including coal, contain carbon and/or hydrogen and may also contain some sulfur.		
The gases released into the atmosphere when a fuel is burned may include carbon dioxide, water		
vapour, carbon monoxide, sulfur dioxide and oxides of nitrogen. Solid particles and unburned		
hydrocarbons may also be released that form particulates in the atmosphere.		
Students should be able to:		
<ul> <li>describe how carbon monoxide, soot (carbon particles), sulphur dioxide and oxides of nitrogen are produced by burning fuels</li> </ul>		
<ul> <li>predict the products of combustion of a fuel given appropriate information about the composition of the fuel and the conditions in which it is used.</li> </ul>		
Properties and effects of atmospheric pollutants		
Carbon monoxide is a toxic gas. It is colourless and odourless and so is not easily detected.		
Sulfur dioxide and oxides of nitrogen cause respiratory problems in humans and cause acid rain.		
Particulates cause global dimming and health problems for humans.		
Students should be able to describe and explain the problems caused by increased amounts of		
these pollutants in the air.		

## C10 - Chemistry of the Atmosphere

#### Part 1 Using the Earth's resources and obtaining potable water

Using the Earth's resources and sustainable development		
Humans use the Earth's resources to provide warmth, shelter, food and transport.		
Natural resources, supplemented by agriculture, provide food, timber, clothing and fuels. Finite		
resources from the Earth, oceans and atmosphere are processed to provide energy and		
materials.		
Chemistry plays an important role in improving agricultural and industrial processes to provide		
new products and in sustainable development, which is development that meets the needs of		
current generations without compromising the ability of future generations to meet their own		
needs.		
Students should be able to: • state examples of natural products that are supplemented or		
replaced by agricultural and synthetic products • distinguish between finite and renewable		
resources given appropriate information.		
Students should be able to: • extract and interpret information about resources from charts,		
graphs and tables		

Potable water		
Water of appropriate quality is essential for life. For humans, drinking water should have		
sufficiently low levels of dissolved salts and microbes.		
Water that is safe to drink is called potable water. Potable water is not pure water in the		
chemical sense because it contains dissolved substances.		
The methods used to produce potable water depend on available supplies of water and local		
conditions. In the United Kingdom (UK), rain provides water with low levels of dissolved		
substances (fresh water) that collects in the ground and in lakes and rivers, and most potable		
water is produced by: • choosing an appropriate source of fresh water • passing the water		
through filter beds • sterilising.		
Sterilising agents used for potable water include chlorine, ozone or ultraviolet light. If supplies of		
fresh water are limited, desalination of salty water or sea water may be required.		
Desalination can be done by distillation or by processes that use membranes such as reverse		
osmosis. These processes require large amounts of energy.		
Students should be able to: • distinguish between potable water and pure water • describe the		
differences in treatment of ground water and salty water • give reasons for the steps used to		
produce potable water.		
Required practical 8: analysis and purification of water samples from different sources, including		
pH, dissolved solids and distillation.		

Waste water treatment		
Urban lifestyles and industrial processes produce large amounts of waste water that require		
treatment before being released into the environment.		
Sewage and agricultural waste water require removal of organic matter and harmful microbes.		
Industrial waste water may require removal of organic matter and harmful chemicals.		
Sewage treatment includes: • screening and grit removal • sedimentation to produce sewage		

sludge and effluent • anaerobic digestion of sewage sludge • aerobic biological treatment of		
effluent.		
Students should be able to comment on the relative ease of obtaining potable water from waste,		
ground and salt water.		

Alternative methods of extracting metals (HT only)		
The Earth's resources of metal ores are limited.		
Copper ores are becoming scarce and new ways of extracting copper from low-grade ores		
include phytomining, and bioleaching.		
These methods avoid traditional mining methods of digging, moving and disposing of large		
amounts of rock.		
Phytomining uses plants to absorb metal compounds. The plants are harvested and then burned		
to produce ash that contains metal compounds.		
Bioleaching uses bacteria to produce leachate solutions that contain metal compounds. The		
metal compounds can be processed to obtain the metal. For example, copper can be obtained		
from solutions of copper compounds by displacement using scrap iron or by electrolysis.		
Students should be able to evaluate alternative biological methods of metal extraction, given		
appropriate information.		

#### Part 2 Life cycle assessment and recycling

Life cycle assessment		
Life cycle assessments (LCAs) are carried out to assess the environmental impact of products in		
each of these stages: $\bullet$ extracting and processing raw materials $\bullet$ manufacturing and packaging $\bullet$		
use and operation during its lifetime • disposal at the end of its useful life, including transport		
and distribution at each stage.		
Use of water, resources, energy sources and production of some wastes can be fairly easily		
quantified. Allocating numerical values to pollutant effects is less straightforward and requires		
value judgements, so LCA is not a purely objective process.		
Selective or abbreviated LCAs can be devised to evaluate a product but these can be misused to		
reach pre-determined conclusions, eg in support of claims for advertising purposes.		
Students should be able to carry out simple comparative LCAs for shopping bags made from		
plastic and paper.		

Ways of reducing the use of resources		
The reduction in use, reuse and recycling of materials by end users reduces the use of limited		
resources, use of energy sources, waste and environmental impacts		
Metals, glass, building materials, clay ceramics and most plastics are produced from limited raw		
materials. Much of the energy for the processes comes from limited resources.		
Obtaining raw materials from the Earth by quarrying and mining causes environmental impacts.		
Some products, such as glass bottles, can be reused.		
Glass bottles can be crushed and melted to make different glass products		
Other products cannot be reused and so are recycled for a different use.		
Metals can be recycled by melting and recasting or reforming into different products.		
The amount of separation required for recycling depends on the material and the properties		
required of the final product. For example, some scrap steel can be added to iron from a blast		

furnace to reduce the amount of iron that needs to be extracted from iron ore.		
Students should be able to evaluate ways of reducing the use of limited resources, given		
appropriate information.
